1 Submanifolds of $\mathbb{R}^n$

1.1 Preliminaries

To begin, we'll recall some facts about the topology of $\mathbb{R}^n$ and vector-valued functions.

In this course, we'll be working with the metric topology with respect to the Euclidean norm (or metric). Let $x = (x_1, \ldots, x_n)$, $y = (y_1, \ldots, y_n) \in \mathbb{R}^n$. The **Euclidean norm** is defined to be

$$\|x\| = \sqrt{x_1^2 + \cdots + x_n^2},$$

and **Euclidean distance** is given by

$$\operatorname{dist}(x, y) = \|y - x\| = \sqrt{(y_1 - x_1)^2 + \cdots + (y_n - x_n)^2}.$$

We define the **open ball** of radius $r > 0$ centered at $x \in \mathbb{R}^n$ by

$$B_r(x) := \{y \in \mathbb{R}^n : \operatorname{dist}(x, y) < r\} \subset \mathbb{R}^n.$$

A **topology** on $\mathbb{R}^n$ is a collection $\mathcal{U} = \{U_\alpha\}_{\alpha \in A}$ of subsets $U_\alpha \subset \mathbb{R}^n$ that satisfy the following properties.

(i) $\varnothing$ and $\mathbb{R}^n$ are in $\mathcal{U}$.

(ii) For any subcollection $\mathcal{V} = \{U_\beta\}_{\beta \in B}$ with $U_\beta \in \mathcal{U}$ for all $\beta \in B$, we have $\bigcup_{\beta \in B} U_\beta \in \mathcal{U}$.

(iii) For any *finite* subcollection $\{U_{\alpha_1}, \ldots, U_{\alpha_m}\} \subset \mathcal{U}$, we have $\bigcap_{i=1}^m U_{\alpha_i} \in \mathcal{U}$.

The sets $U_\alpha \in \mathcal{U}$ are called the **open sets** of the topology; their complements $F_\alpha = \mathbb{R}^n \setminus U_\alpha$ are called the **closed sets**.

Note that the sets $\varnothing$ and $\mathbb{R}^n$ are both open and closed. Moreover, the notion of a topology can be extended to more general sets X, not just $\mathbb{R}^n$. A topology can also be defined starting with closed sets, but we prefer to work with open sets because many nice properties, such as differentiability, are better described with them.

Under the metric topology, we say that a set $A \subset \mathbb{R}^n$ is **open** if $A = \varnothing$ or if for all $p \in A$, there exists $r > 0$ such that $B_r(p) \subset A$. Moreover, A is **closed** if its complement $A^c = \mathbb{R}^n \setminus A$ is open. (We leave it as an exercise to show that this is indeed a topology.)

For example, the open balls $B_r(x)$ are open sets for all $x \in \mathbb{R}^n$ and $r > 0$. Indeed, for any point $p \in B_r(x)$, one sees that by picking $r' = (r - \|p - x\|)/2$, we have $B_{r'}(p) \subset B_r(x)$.

In general, open sets are described with strict inequalities, while closed sets are described using equality or inclusive inequalities. However, note that most sets are neither open nor closed, such as the half-open interval $U = (-1, 1]$ over $\mathbb{R}$.

The metric topology is not the only topology on $\mathbb{R}^n$; one example is the one consisting of only the sets $\mathcal{U} = \{\varnothing, \mathbb{R}^n\}$. However, we generally want more open sets to work with since we might want to know the behaviour of functions around a point $p \in \mathbb{R}^n$. If the only non-empty open set we had was $\mathbb{R}^n$, then this would apply to all points in $\mathbb{R}^n$, which does not yield a lot of information.

Let $p \in \mathbb{R}^n$. The previous paragraph leads us to the definition of an **open neighbourhood** of p, which is just an open set $U \subset \mathbb{R}^n$ such that $p \in U$.

We now turn our discussion to vector-valued functions. Let $U \subset \mathbb{R}^n$ and consider the vector-valued function

$$\begin{aligned} F : U \subset \mathbb{R}^n &\to B \subset \mathbb{R}^m \\ x = (x_1, \ldots, x_n) &\mapsto (F_1(x), \ldots, F_m(x)). \end{aligned}$$

Then F is continuous if and only if the component functions $F_i : U \to \mathbb{R}$ are continuous for all $i = 1, \ldots, m$.

We say that F is a **homeomorphism** if it is a continuous bijection whose inverse

$$F^{-1} : B \subset \mathbb{R}^m \to U \subset \mathbb{R}^n$$

is also continuous. For example, the identity map $\mathrm{Id}_{\mathbb{R}^n} : \mathbb{R}^n \to \mathbb{R}^n$ and the function $f : \mathbb{R} \to \mathbb{R}$ defined by $f(x) = x^3$ are both homeomorphisms.

It is a known fact that homeomorphisms map open sets to open sets and closed sets to closed sets. This follows from the topological characterization of continuity, which states that F is continuous if and only if for every open (respectively closed) set $V \subset \mathbb{R}^m$, we have that $F^{-1}(V)$ is open (respectively closed). In fact, homeomorphisms preserve much more structure than this, as we'll see later.

1.2 Topological Submanifolds of $\mathbb{R}^n$

We now define the main object we'll be working with in this course.

Definition 1.1

A k**-dimensional topological submanifold** (or **topological** k**-submanifold**) of $\mathbb{R}^n$ is a subset $M \subset \mathbb{R}^n$ such that for every $p \in M$, there exists an open neighbourhood V of p in $\mathbb{R}^n$, an open set $U \subset \mathbb{R}^k$, and a homeomorphism

$$\alpha : U \subset \mathbb{R}^k \to V \cap M \subset \mathbb{R}^n.$$

For example, $\mathbb{R}^n$ is a topological n-submanifold of $\mathbb{R}^n$ by taking $U = V = \mathbb{R}^n$ and $\alpha = \mathrm{Id}_{\mathbb{R}^n}$. Any open set $W \subset \mathbb{R}^n$ is a topological n-submanifold of $\mathbb{R}^n$ by taking $U = V = W$ and $\alpha = \mathrm{Id}_W$.
